May 7, 2019

### 1 Face Generation

In this project, you'll define and train a DCGAN on a dataset of faces. Your goal is to get a generator network to generate *new* images of faces that look as realistic as possible!

The project will be broken down into a series of tasks from **loading in data to defining and training adversarial networks**. At the end of the notebook, you'll be able to visualize the results of your trained Generator to see how it performs; your generated samples should look like fairly realistic faces with small amounts of noise.

### 1.0.1 Get the Data

You'll be using the CelebFaces Attributes Dataset (CelebA) to train your adversarial networks.

This dataset is more complex than the number datasets (like MNIST or SVHN) you've been working with, and so, you should prepare to define deeper networks and train them for a longer time to get good results. It is suggested that you utilize a GPU for training.

### 1.0.2 Pre-processed Data

Since the project's main focus is on building the GANs, we've done *some* of the pre-processing for you. Each of the CelebA images has been cropped to remove parts of the image that don't include a face, then resized down to 64x64x3 NumPy images. Some sample data is show below.

If you are working locally, you can download this data by clicking here

This is a zip file that you'll need to extract in the home directory of this notebook for further loading and processing. After extracting the data, you should be left with a directory of data processed\_celeba\_small/

```
import numpy as np
import problem_unittests as tests
#import helper
%matplotlib inline
```

### 1.1 Visualize the CelebA Data

The CelebA dataset contains over 200,000 celebrity images with annotations. Since you're going to be generating faces, you won't need the annotations, you'll only need the images. Note that these are color images with 3 color channels (RGB) each.

### 1.1.1 Pre-process and Load the Data

Since the project's main focus is on building the GANs, we've done *some* of the pre-processing for you. Each of the CelebA images has been cropped to remove parts of the image that don't include a face, then resized down to 64x64x3 NumPy images. This *pre-processed* dataset is a smaller subset of the very large CelebA data.

There are a few other steps that you'll need to **transform** this data and create a **DataLoader**.

Exercise: Complete the following get\_dataloader function, such that it satisfies these requirements:

- Your images should be square, Tensor images of size image\_size x image\_size in the x and y dimension.
- Your function should return a DataLoader that shuffles and batches these Tensor images.

**ImageFolder** To create a dataset given a directory of images, it's recommended that you use PyTorch's ImageFolder wrapper, with a root directory processed\_celeba\_small/ and data transformation passed in.

```
transforms.CenterCrop(image_size),
    transforms.ToTensor(),
    \#transforms.Normalize(mean=(0.5, 0.5, 0.5), std=(0.5, 0.5, 0.5))
])
dataset = datasets.ImageFolder(data_dir, transform=transform)
# TODO: Implement function and return a dataloader
data_loader = torch.utils.data.DataLoader(dataset=dataset,
                                         batch_size=batch_size,
                                         shuffle=True)
```

return data\_loader

### 1.2 Create a DataLoader

Exercise: Create a DataLoader celeba\_train\_loader with appropriate hyperparameters. Call the above function and create a dataloader to view images. \* You can decide on any reasonable batch\_size parameter \* Your image\_size must be 32. Resizing the data to a smaller size will make for faster training, while still creating convincing images of faces!

```
In [4]: # Define function hyperparameters
        batch_size = 128
        img_size = 32
        DON'T MODIFY ANYTHING IN THIS CELL THAT IS BELOW THIS LINE
        # Call your function and get a dataloader
        celeba_train_loader = get_dataloader(batch_size, img_size)
```

Next, you can view some images! You should seen square images of somewhat-centered faces. Note: You'll need to convert the Tensor images into a NumPy type and transpose the dimensions to correctly display an image, suggested imshow code is below, but it may not be perfect.

```
In [8]: # helper display function
        def imshow(img):
            npimg = img.numpy()
            plt.imshow(np.transpose(npimg, (1, 2, 0)))
        11 11 11
        DON'T MODIFY ANYTHING IN THIS CELL THAT IS BELOW THIS LINE
        # obtain one batch of training images
        dataiter = iter(celeba_train_loader)
        images, _ = dataiter.next() # _ for no labels
        # plot the images in the batch, along with the corresponding labels
```

```
fig = plt.figure(figsize=(20, 4))
plot_size=20
for idx in np.arange(plot_size):
    ax = fig.add_subplot(2, plot_size/2, idx+1, xticks=[], yticks=[])
    imshow(images[idx])
```

Exercise: Pre-process your image data and scale it to a pixel range of -1 to 1 You need to do a bit of pre-processing; you know that the output of a tanh activated generator will contain pixel values in a range from -1 to 1, and so, we need to rescale our training images to a range of -1 to 1. (Right now, they are in a range from 0-1.)

```
In [9]: # TODO: Complete the scale function
        def scale(x, feature_range=(-1, 1)):
            ''' Scale takes in an image x and returns that image, scaled
               with a feature_range of pixel values from -1 to 1.
               This function assumes that the input x is already scaled from 0-1.'''
            # assume x is scaled to (0, 1)
            \# scale to feature_range and return scaled x
            min, max = feature_range
            x = x * (max - min) + min
            return x
In [10]: """
         DON'T MODIFY ANYTHING IN THIS CELL THAT IS BELOW THIS LINE
         # check scaled range
         # should be close to -1 to 1
         img = images[0]
         scaled_img = scale(img)
         print('Min: ', scaled_img.min())
         print('Max: ', scaled_img.max())
Min: tensor(-0.8118)
Max: tensor(0.8588)
```

### 2 Define the Model

A GAN is comprised of two adversarial networks, a discriminator and a generator.

### 2.1 Discriminator

Your first task will be to define the discriminator. This is a convolutional classifier like you've built before, only without any maxpooling layers. To deal with this complex data, it's suggested you use a deep network with **normalization**. You are also allowed to create any helper functions that may be useful.

### **Exercise: Complete the Discriminator class**

- The inputs to the discriminator are 32x32x3 tensor images
- The output should be a single value that will indicate whether a given image is real or fake

```
In [11]: import torch.nn as nn
         import torch.nn.functional as F
In [12]: def conv(in_channels, out_channels, kernel_size, stride=2, padding=1, batch_norm=True):
             Creates a convolutional layer, with optional batch normalization.
             layers=[]
             conv_layer = nn.Conv2d(in_channels, out_channels,
                                   kernel_size, stride, padding, bias=False)
             # append conv layer
             layers.append(conv_layer)
             if batch_norm:
                 # append batchnorm layer
                 layers.append(nn.BatchNorm2d(out_channels))
             # using Sequential container
             return nn.Sequential(*layers)
In [13]: class Discriminator(nn.Module):
             def __init__(self, conv_dim):
                 Initialize the Discriminator Module
                 :param conv_dim: The depth of the first convolutional layer
                 super(Discriminator, self).__init__()
                 # complete init function
                 self.conv_dim = conv_dim
```

```
self.conv1 = nn.Conv2d(3, conv_dim, kernel_size=4, stride=2, padding=1, bias=Fa
        self.batch_norm1 = nn.BatchNorm2d(conv_dim)
        self.conv2 = nn.Conv2d(conv_dim, conv_dim*2,kernel_size=4, stride=2, padding=1,
        self.batch_norm2 = nn.BatchNorm2d(conv_dim*2)
        self.conv3 = nn.Conv2d(conv_dim*2, conv_dim*4, kernel_size=4, stride=2, padding
        self.batch_norm3 = nn.BatchNorm2d(conv_dim*4)
        self.conv4 = nn.Conv2d(conv_dim*4, conv_dim*8, kernel_size=4, stride=2, padding
        self.batch_norm4 = nn.BatchNorm2d(conv_dim*8)
        self.conv5 = nn.Conv2d(conv_dim*8, conv_dim*16, kernel_size=4, stride=2, paddim
        self.fc = nn.Linear(conv_dim*4*4, 1)
    def forward(self, x):
        Forward propagation of the neural network
        :param x: The input to the neural network
        :return: Discriminator logits; the output of the neural network
        HHHH
        # define feedforward behavior
        x = F.leaky_relu(self.batch_norm1(self.conv1(x)), 0.2)
        x = F.leaky_relu(self.batch_norm2(self.conv2(x)), 0.2)
        x = F.leaky_relu(self.batch_norm3(self.conv3(x)), 0.2)
        x = F.leaky_relu(self.batch_norm4(self.conv4(x)), 0.2)
        x = self.conv5(x)
        # flatten
        x = x.view(-1, self.conv_dim*4*4)
        # final output layer
        x = F.sigmoid(self.fc(x))
        return x

### 2.2 Generator

The generator should upsample an input and generate a *new* image of the same size as our training data 32x32x3. This should be mostly transpose convolutional layers with normalization applied to the outputs.

### **Exercise: Complete the Generator class**

The inputs to the generator are vectors of some length z\_size

The output should be a image of shape 32x32x3

```
In [14]: def deconv(in_channels, out_channels, kernel_size, stride=2, padding=1, batch_norm=True
             layers=[]
             transpose_conv_layer = nn.ConvTranspose2d(in_channels, out_channels,
                                                      kernel_size, stride, padding, bias=False)
             # append transpose convolutional layer
             layers.append(transpose_conv_layer)
             if batch_norm:
                 # append batchnorm layer
                 layers.append(nn.BatchNorm2d(out_channels))
             return nn.Sequential(*layers)
In [15]: class Generator(nn.Module):
             def __init__(self, z_size, conv_dim):
                 Initialize the Generator Module
                 :param z_size: The length of the input latent vector, z
                 :param conv_dim: The depth of the inputs to the *last* transpose convolutional
                 super(Generator, self).__init__()
                 self.conv_dim = conv_dim
                 # first, fully-connected layer
                 self.fc = nn.Linear(z_size, conv_dim*8*2*2)
                 # transpose conv layers
                 self.deconv1 = deconv(conv_dim*8, conv_dim*4, 4)
                 self.deconv2 = deconv(conv_dim*4, conv_dim*2, 4)
                 self.deconv3 = deconv(conv_dim*2, conv_dim, 4)
                 self.deconv4 = deconv(conv_dim, 3, 4, batch_norm=False)
             def forward(self, x):

### 2.3 Initialize the weights of your networks

To help your models converge, you should initialize the weights of the convolutional and linear layers in your model. From reading the original DCGAN paper, they say: > All weights were initialized from a zero-centered Normal distribution with standard deviation 0.02.

So, your next task will be to define a weight initialization function that does just this!

You can refer back to the lesson on weight initialization or even consult existing model code, such as that from the networks.py file in CycleGAN Github repository to help you complete this function.

### Exercise: Complete the weight initialization function

- This should initialize only **convolutional** and **linear** layers
- Initialize the weights to a normal distribution, centered around 0, with a standard deviation of 0.02.
- The bias terms, if they exist, may be left alone or set to 0.

```
In [16]: def weights_init_normal(m):
    """
    Applies initial weights to certain layers in a model .
    The weights are taken from a normal distribution
    with mean = 0, std dev = 0.02.
        :param m: A module or layer in a network
        """

    # classname will be something like:
    # `Conv`, `BatchNorm2d`, `Linear`, etc.
    classname = m.__class__.__name__

# TODO: Apply initial weights to convolutional and linear layers
    if hasattr(m, 'weight') and (classname.find('Conv') != -1 or classname.find('Linear m.weight.data.normal_(0.0, 0.02)
```

```
# The bias terms, if they exist, set to 0
if hasattr(m, 'bias') and m.bias is not None:
    m.bias.data.zero_()
```

### Build complete network

Define your models' hyperparameters and instantiate the discriminator and generator from the classes defined above. Make sure you've passed in the correct input arguments.

```
In [17]: """
         DON'T MODIFY ANYTHING IN THIS CELL THAT IS BELOW THIS LINE
         def build_network(d_conv_dim, g_conv_dim, z_size):
             # define discriminator and generator
             D = Discriminator(d_conv_dim)
             G = Generator(z_size=z_size, conv_dim=g_conv_dim)
             # initialize model weights
             D.apply(weights_init_normal)
             G.apply(weights_init_normal)
             print(D)
             print()
             print(G)
             return D, G
```

```
Exercise: Define model hyperparameters
In [18]: # Define model hyperparams
         d_{conv_dim} = 64

  )
)
```

### 2.4.1 Training on GPU

Check if you can train on GPU. Here, we'll set this as a boolean variable train\_on\_gpu. Later, you'll be responsible for making sure that >\* Models, \* Model inputs, and \* Loss function arguments

Are moved to GPU, where appropriate.

### 2.5 Discriminator and Generator Losses

Now we need to calculate the losses for both types of adversarial networks.

### 2.5.1 Discriminator Losses

- For the discriminator, the total loss is the sum of the losses for real and fake images, d\_loss = d\_real\_loss + d\_fake\_loss.
- Remember that we want the discriminator to output 1 for real images and 0 for fake images, so we need to set up the losses to reflect that.

### 2.5.2 Generator Loss

The generator loss will look similar only with flipped labels. The generator's goal is to get the discriminator to *think* its generated images are *real*.

Exercise: Complete real and fake loss functions You may choose to use either cross entropy or a least squares error loss to complete the following real\_loss and fake\_loss functions.

```
In [20]: def real_loss(D_out):
             '''Calculates how close discriminator outputs are to being real.
                param, D_out: discriminator logits
                return: real loss'''
             batch_size = D_out.size(0)
             labels = torch.ones(batch_size) * 0.9
             if train_on_gpu:
                 labels = labels.cuda()
             criterion = nn.BCEWithLogitsLoss()
             loss = criterion(D_out.squeeze(), labels)
             return loss
         def fake loss(D out):
             '''Calculates how close discriminator outputs are to being fake.
                param, D_out: discriminator logits
                return: fake loss'''
             batch_size = D_out.size(0)
             labels = torch.zeros(batch_size) # fake labels = 0
             if train_on_gpu:
                 labels = labels.cuda()
             criterion = nn.BCEWithLogitsLoss()
             # calculate loss
             loss = criterion(D_out.squeeze(), labels)
             return loss
```

### 2.6 Optimizers

**Exercise: Define optimizers for your Discriminator (D) and Generator (G)** Define optimizers for your models with appropriate hyperparameters.

```
In [21]: import torch.optim as optim

# Create optimizers for the discriminator D and generator G
d_optimizer = optim.Adam(D.parameters(), lr=0.0002, betas=(0.5, 0.999))
g_optimizer = optim.Adam(G.parameters(), lr=0.0002, betas=(0.5, 0.999))
```

### 2.7 Training

Training will involve alternating between training the discriminator and the generator. You'll use your functions real\_loss and fake\_loss to help you calculate the discriminator losses.

- You should train the discriminator by alternating on real and fake images
- Then the generator, which tries to trick the discriminator and should have an opposing loss function

**Saving Samples** You've been given some code to print out some loss statistics and save some generated "fake" samples.

**Exercise:** Complete the training function Keep in mind that, if you've moved your models to GPU, you'll also have to move any model inputs to GPU.

```
In [22]: def train(D, G, n_epochs, print_every=50):
             '''Trains adversarial networks for some number of epochs
                param, D: the discriminator network
                param, G: the generator network
                param, n_epochs: number of epochs to train for
                param, print_every: when to print and record the models' losses
                return: D and G losses'''
             # move models to GPU
             if train_on_gpu:
                 D.cuda()
                 G.cuda()
             # keep track of loss and generated, "fake" samples
             samples = []
             losses = []
             # Get some fixed data for sampling. These are images that are held
             # constant throughout training, and allow us to inspect the model's performance
             sample_size=16
             fixed_z = np.random.uniform(-1, 1, size=(sample_size, z_size))
```

```
fixed_z = torch.from_numpy(fixed_z).float()
# move z to GPU if available
if train_on_gpu:
   fixed_z = fixed_z.cuda()
# epoch training loop
for epoch in range(n_epochs):
   # batch training loop
   for batch_i, (real_images, _) in enumerate(celeba_train_loader):
       batch_size = real_images.size(0)
       real_images = scale(real_images)
       # -----
                YOUR CODE HERE: TRAIN THE NETWORKS
       d_optimizer.zero_grad()
       if train_on_gpu:
           real_images = real_images.cuda()

### 2.8 Training loss

Plot the training losses for the generator and discriminator, recorded after each epoch.

### 2.9 Generator samples from training

View samples of images from the generator, and answer a question about the strengths and weaknesses of your trained models.

# 2.9.1 Question: What do you notice about your generated samples and how might you improve this model?

When you answer this question, consider the following factors: \* The dataset is biased; it is made of "celebrity" faces that are mostly white \* Model size; larger models have the opportunity to learn

more features in a data feature space \* Optimization strategy; optimizers and number of epochs affect your final result

**Answer:** (Write your answer in this cell)

I think that human face has very complicated and complex features and it's hard to extract these features with a simple model. I used 4 convolutional and 4 transpose convolutional layers. But some of the images that the generator generated are unrecognizable faces. I guess it needs to have one more convolutional layer. The conv\_dim for the generator and discriminator is set to 64. To extract more sophisticated features, I guess it needs to be set up to higher dimentions(or depth). One of the Udacity mentors said that DCGAN is not a typical network where reduction in loss will point towards a better model. I don't know why it isn't so I'm not sure if higher epochs makes the generaotor generate more accurate and realistic faces. I'm wondering what if the CelebA dataset doesn't contain some images, for example, which a hat, a hand, or sunglasses is covering his or her face, how the generated images would be.

### 2.9.2 Submitting This Project

When submitting this project, make sure to run all the cells before saving the notebook. Save the notebook file as "dlnd\_face\_generation.ipynb" and save it as a HTML file under "File" -> "Download as". Include the "problem\_unittests.py" files in your submission.
